Design of the Irrigation System

Automatic irrigation systems are required for constructed landscape areas on all Lots. In addition to automatic irrigation systems, water capture systems used to harvest run-off for future re-use are an appropriate way to provide water for plants in managed amounts. An irrigation design professional should be consulted to provide an efficient watering system that promotes healthy plant growth and minimizes water loss due to run-off and evapotranspiration.

General Irrigation Design Considerations

- All landscape areas (private and other) shall be maintained on a permanent, automatic drip irrigation system.
- Salvaged or nursery-grown native trees and cacti must receive supplemental water, consistent with local standards.
- Valve or other flush-mounted boxes shall match the color of the ground surface (desert tan or green when in turf).
- Locate valve boxes, flush caps, and so on in inconspicuous areas of the site, no further than three (3) feet away from the Home. Set boxes on at ground to minimize visibility.
- Conceal boxes from view with small shrubs. Avoid setting boxes on a tilted plane; instead, always set boxes at.
- Locate wall-mounted or above-ground equipment behind rear yard enclosure walls or within refuse enclosure walls.
- Paint free-standing or wall-mounted equipment to match the exterior color of the house or the walls on which they are mounted.

Valves

- Different plant species require varying amounts of water and frequency of application. Proper valving can significantly reduce maintenance and water costs. Separate valves are required for:
 - Trees
 - Low-water-use shrubs
 - Ornamental shrubs
 - Turf
 - Pots or Garden
- Additional valves should be considered to accommodate exposure differences. For example, most groundcovers and shrubs planted in a shady zone will require less water than the same plant placed in an exposure that receives full sun. If both plants receive the same quantity and frequency of water, the plant in the shady location will not have an opportunity to dry out and may rot while the plant in full sun will suffer from infrequent watering.

Turf Irrigation

- Spray irrigation is limited to turf areas only.
- If both rotors and low trajectory heads are needed to irrigate turf areas, provide separate valves for each to maximize control and efficiency of the system.
- Runoff into streets, onto sidewalks, onto neighboring properties, or into natural areas not previously part of the site drainage pattern is prohibited.
- Offset heads six (6) to twelve (12) inches from pavement.

Irrigation Installation in Native Areas

For Homes on Custom Lots along Reata Wash only, supplemental landscape improvements may be required in native areas. In the event that landscape and irrigation are required to be provided in native areas, the following shall apply:

- Locate all mainlines, and as many lateral lines as possible, within the existing disturbed areas. Minimize trenching for irrigation to new plants to just those natural areas of seams between existing plantings.

Irrigation for Performance and Reduced Consumption

Spray irrigation can create significant runoff after only a few minutes of operation. Homeowners must manage their irrigation water properly by:

- Properly grading and sloping the land to hold runoff.
- Preparing the soil prior to planting to ensure good drainage.
- Selecting heads to fit the size and configuration of the turf area.
- Managing the duration of the irrigation cycle to avoid runoff conditions. Select several short irrigation intervals during the day rather than one long setting.
